Interactive Trace Replay for Event-B Models

Jan Gruteser, Michael Leuschel

ProB

- Model checker, animator, and constraint solver
- High-level formal specification languages (like Event-B and TLA+)
- Tooling:
 - CLI
 - ProB Java API
 - ProB Rodin Plugin
 - ProB2-UI: VisB, SimB, trace replay
- Developed by STUPS group at HHU Düsseldorf (open source)
- Focus of this talk: Trace Export and Replay

Motivation

- ProB allows to store and replay traces (automatically)
 - sequence of transitions
 - validate the model's behaviour at different stages of its development
- But: often breaking changes between model versions
 - e.g. renamed variables/events
 - Old traces can only be partially replayed (or not at all)
 - Refactoring/repairing traces can be hard for complex models
- Idea: instead of trying to replay everything automatically, let the user decide interactively in case of conflicts

Position A	Transition
0	root
1	SETUP_CONSTANTS
2	INITIALISATION
3	close_elevator_door
4	move_to_floor(f=1)
5	open_elevator_door
6	close_elevator_door
7	move_to_floor(f=4)
8	open_elevator_door
9	close_elevator_door
10	move_to_floor(f=-1)
11	open_elevator_door

Use Cases

1. Refinement of Traces

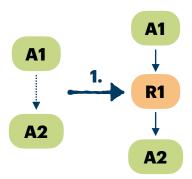

Insert new trace steps between two abstract steps by manual animation of new or refined events

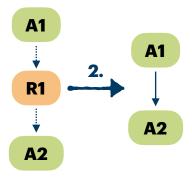

2. Abstraction of Traces

Skip steps with unavailable concrete events

3. Refactoring/Repairing of Traces

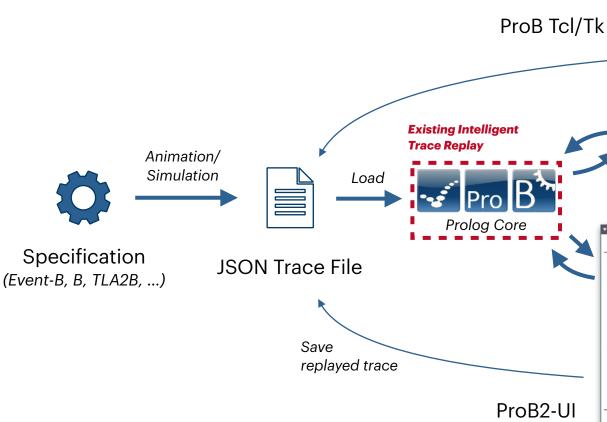

Refactor/repair traces of complex models after major changes

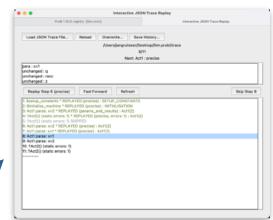

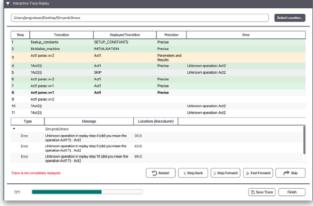

Overview

So far

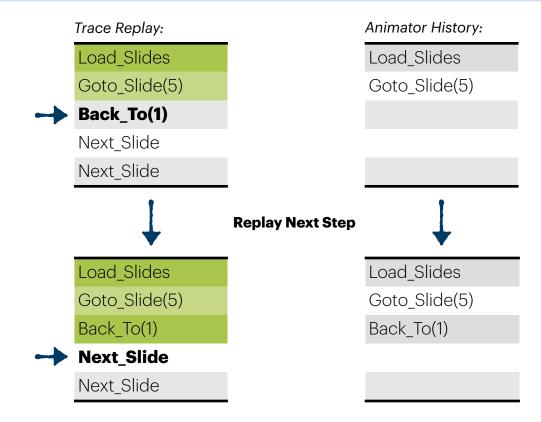

- "Intelligent" trace replay, automatic replay without user input
- Tries to resolve possible failure scenarios with different precision
 - 1. Perfect replay: matching operation name, parameters and variable values after the trace step
 - 2. Parameters: matching operation name and parameters
 - 3. Operation name: matching operation name
 - 4. Use another operation with the same effect (e.g. when an operation has been renamed)
 - 5. Skip steps where the original operation is unavailable
- This is not always possible.
- We combine the existing logic with the interactive replay
 - conflicts that cannot be handled can be resolved by the modeller
 - add / change / remove trace steps flexibly during replay

- Two states:
 - Current position in the replayed trace
 - State/history of the animator
- Based on this:
 - Replay <u>next step</u> using a matching transition, if possible (selected by intelligent replay as before)
 - Fast Forward": <u>automatic replay</u> until the next step cannot be replayed (this is basically the previous implementation)
 - Skip the current trace step, always possible
 - Add <u>manual animation</u> steps anywhere in the trace using the animator
 - <u>Undo</u> the last replayed transition (from manual animation or replayed)

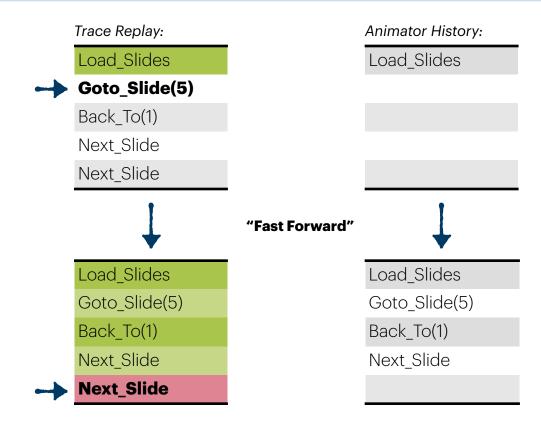

- Two states:
 - Current position in the replayed trace
 - State/history of the animator
- Based on this:
 - Replay <u>next step</u> using a matching transition, if possible (selected by intelligent replay as before)
 - "Fast Forward": <u>automatic replay</u> until the next step cannot be replayed (this is basically the previous implementation)
 - Skip the current trace step, always possible
 - Add <u>manual animation</u> steps anywhere in the trace using the animator
 - <u>Undo</u> the last replayed transition (from manual animation or replayed)

Example: Lift

- Model of a simple lift
- Consider abstraction and first refinement
 - Abstraction has only one event: move_to_floor
 - Refinement adds the cabin door: close door, open door
- We want to replay a trace:
 - created for LiftO on Lift1 (refinement of a trace)
 - created for Lift1 on Lift0 (abstraction of a trace)

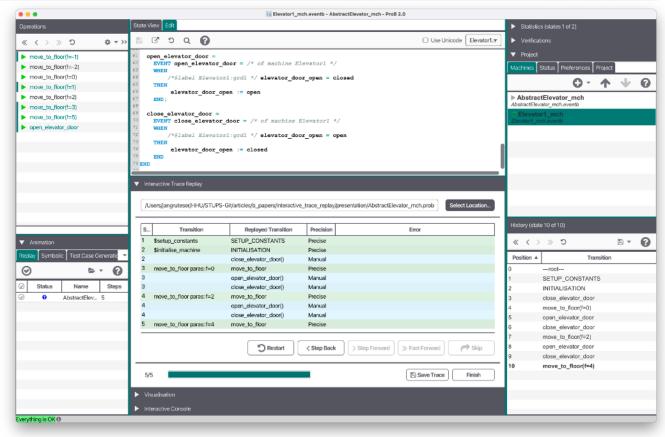

LiftO

Lift1

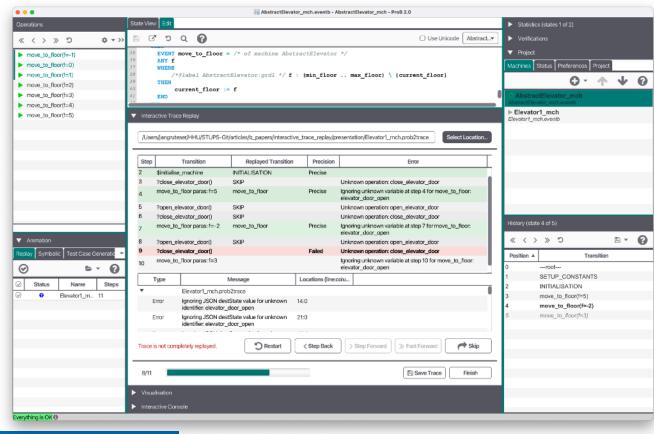

ProB2-UI Example: Refinement of a Trace

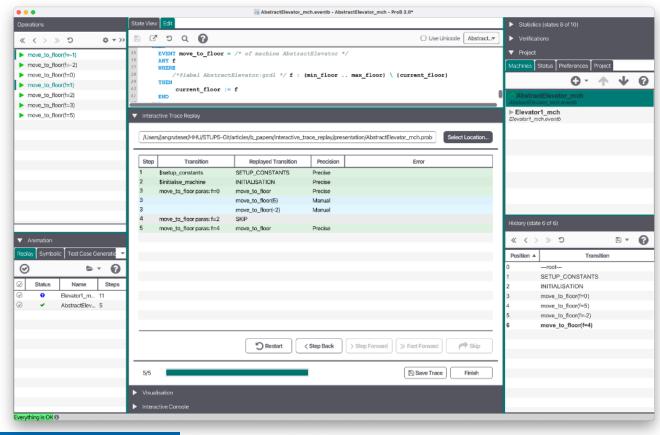

ProB2-UI Example: Abstraction of a Trace

ProB2-UI Example: Refactoring of a Trace

Conclusion

- Interactive trace replay initially motivated by refactoring of trace for complex model
 - Also useful for further applications: abstraction and refinement of traces
- Future Plans:
 - Provide more options how the next transition should be selected
 - Allow the user to select the next replayed transitions explicitly
 - Replace not available operations in the entire trace with another one, e.g. if a operation has been renamed
 - Restrict the replay precision, e.g. allowing only precise replay
- Comments, questions? What other functionality/application would be interesting?
